Preface

DevOps is the combination of cultural philosophies, engineering practices, and tools that increase an organization's ability to deliver applications and services at high velocity and better quality. Over time, several essential practices have emerged when adopting DevOps: **continuous integration (CI)**, **continuous delivery (CD)**, **Infrastructure as Code (IaC)**, and monitoring and logging.

AWS DevOps Engineer Professional Certification Guide is one of the more elaborate and demanding cloud certifications. Organizations with these qualified professionals can ensure speedy delivery of secure, compliant, systems that are highly available and scalable. Moreover, job listings requiring this certification have significantly increased over the past few years.

This book is designed to provide a comprehensive guide to provisioning, operating, and managing distributed systems and services on AWS. It covers a wide range of topics, including implementing and managing continuous delivery systems and methodologies on AWS, implementing and automating security controls, governance processes, and compliance validation, defining and deploying monitoring, metrics, and logging systems on AWS, and implementing systems that are highly available, scalable, and self-healing on AWS. Additionally, it addresses designing, managing, and maintaining tools to automate operational processes on AWS.

This book is intended for all IT professionals who have a basic understanding and experience of the AWS environment and looking forward to stepping into the DevOps domain as an AWS Certified DevOps Engineer. Its particularly attractive to candidates who have failed in the 1st and 2nd attempts of the exams, which comprise more than 50% of the candidates.

Chapter 1: Continuous Integration with CodeCommit and CodeBuild - The chapter explains everything needed for the reader to create a CodeCommit repository to store the code and files securely for the project, including the usage of different CodeCommit CLI commands such as clone a repository, tag repository, create pull request, list pull requests, creating an approval rule for pull request by taking different examples. The chapter also goes into greater detail about AWS CodeBuild service by taking two real-world use-cases. CHAPTER 1

Continuous Integration with CodeCommit and CodeBuild

Introduction

Continuous Integration and Continuous Delivery/Deployment (CI/CD) are two important parts of DevOps. In this process, when commit or changes happen in source code, they go through automated stage gates, all the way from building, testing, deploying the applications from development to production environments, across cloud accounts.

In this chapter, we learn how AWS CodeCommit makes it easy for developers to collaborate on code using secure code repositories and AWS CodeBuild compiles source code, runs tests and produces software packages that are ready to deploy, on a dynamically created build server.

Structure

In this chapter, we will discuss about the following topics in AWS CodeCommit:

- Setup AWS CodeCommit repository
- Security requirements for AWS CodeCommit repository
- Tagging repositories in CodeCommit
- Setting up CodeCommit trigger for SNS Topic
- Setting up CodeCommit trigger for Lambda Function

- Creating a pull request in AWS CodeCommit
- Creating an approver rule for pull request
- AWS CloudShell for DevOps tasks
- Working with private NPM packages in CodeArtifact
- Automated code review with AWS CodeGuru

Here are the topics that we will cover in AWS CodeBuild:

- Building and deploying source code with AWS CodeBuild and S3, building and pushing docker images to AWS **Elastic Container Registry (ECR)**, and configuring an App Runner service

Objectives

After reading this chapter, we will be able to efficiently set up and manage an AWS CodeCommit repository, implement security measures, and utilize various features like tagging and triggers. We will gain a deep understanding of how to create and manage pull requests and approver rules, as well as how to leverage AWS CloudShell and CodeArtifact for DevOps tasks. Additionally, we will master the art of building and deploying source code with AWS CodeBuild and S3, working with Docker images and AWS ECR, and configuring an App Runner Service. By the end of this chapter, we will have acquired the essential skills and knowledge to implement a seamless CI process using AWS CodeCommit and CodeBuild, ultimately enhancing your proficiency in DevOps and cloud-based development practices.

Setup AWS CodeCommit repository

This section discusses the key features of AWS CodeCommit such as creating a repository, commit files to the repository, cloning a repository, pushing files to the repository, creating pull requests, tagging repositories and adding triggers into the repository.

Creating a Repository using console

We can either use AWS Console or **AWS Command Line Interface (AWS CLI)** to create an empty repository. Go to the **Repositories** page from **CodeCommit** console and click on **Create Repository**. Enter the name of **repository**, **description** (optional), add **tags** (optional), select **Enable Amazon CodeGuru Reviewer for Java and Python** (optional), and click **Create** as shown in *Figure 1.1*:

Developer Tools > CodeCommit > Repositories > Create repository

Create repository

Create a secure repository to store and share your code. Begin by typing a repository name and a description for your repository. Repository names are included in the URLs for that repository.

Figure 1.1: Create a repository

Creating a repository using AWS CLI

Use `create-repository` command to create a repository from AWS CLI by providing a unique name for the repository (with `--repository-name` option), and some optional comments about the repository (with `--repository-description` option):

1. `aws codecommit create-repository --repository-name MyFirstRepo \`
2. `--repository-description "My First CodeCommit Repository"`

If the command is successful, it displays the following output:

3. `{`
4. `"repositoryMetadata": {`
5. `"accountId": "958651443844",`
6. `"repositoryId": "8d9914d9-bcb1-4f3a-bbd5-62320273a956",`
7. `"repositoryName": "MyFirstRepo",`
8. `"repositoryDescription": "My First CodeCommit Repository",`
9. `"lastModifiedDate": "2022-10-13T21:32:10.432000+00:00",`
10. `"creationDate": "2022-10-13T21:32:10.432000+00:00",`

```
11.         "cloneUrlHttp": "https://git-codecommit.us-east-1.amazonaws.  
           com/v1/repos/MyFirstRepo",  
12.         "cloneUrlSsh": "ssh://git-codecommit.us-east-1.amazonaws.  
           com/v1/repos/MyFirstRepo",  
13.         "Arn": "arn:aws:codecommit:us-east-1:958651443844:MyFirstRepo"  
14.     }  
15. }
```

Creating a commit

We can use Git client, AWS CLI or CodeCommit Console to create a commit in CodeCommit repository. In this example, we will show how to commit using Git client which is the most preferred method used by the developers to push the changes in AWS CodeCommit repository.

Use the following steps to commit a file in **MyFirstRepo** CodeCommit repository:

1. Ensure you are on the right branch otherwise, run **git branch** which will display the list of branches. If you are not in the right branch run **git checkout branch-name** to switch to the intended branch.
2. Make a change to the branch like adding, updating, or deleting a file. For example, create a test file (**test.txt**) with some text: **Hello to DevOps World!**.
3. Run **git status** command and it will alert you that there are some untracked files.
4. Run **git add test.txt**. This command will include a change in the working directory to the staging area.
5. If we run **git status**, it will alert that there are some changes to be committed.
6. Finally run **git commit -m "Some comments to the commit"**. If we run git status now git will alert that commit is ready to be pushed from local repo to CodeCommit repository.
7. If the changes in the file look good, then run **git push origin remote-branch** which will push the file to CodeCommit repository

Cloning a repository

Select the repository which you want to connect and choose one of the following methods shown in the following drop-down populated:

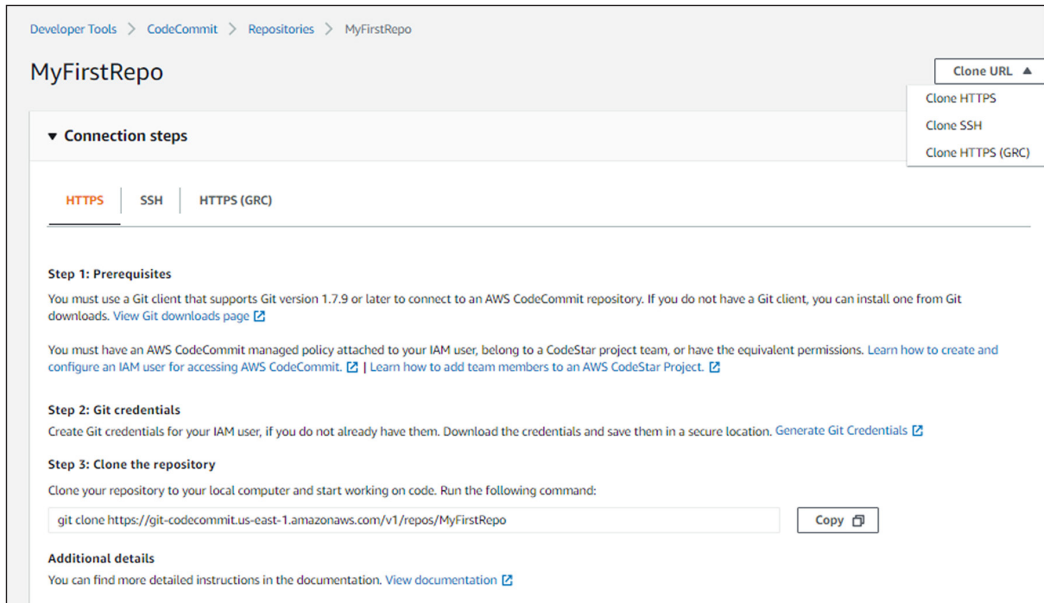

Figure 1.2: Clone a repository

1. **Clone HTTPS:** Use this option if you want to use your git credentials obtained along with your IAM user details from AWS Administrator:
`https://git-codecommit.us-east-1.amazonaws.com/v1/repos/MyFirstRepo`
2. **Clone SSH:** Use this option if you want to use SSH public/private key pair with your IAM User:
`ssh://git-codecommit.us-east-1.amazonaws.com/v1/repos/MyFirstRepo`
3. **Clone HTTPS (GRC):** Use this option if you want to use **git-remote-codecommit** on your local machine. This method is recommended if you want to support connections made with federated access, identity providers, and temporary credentials:
`codecommit::us-east-1://MyFirstRepo`

Security requirements for AWS CodeCommit repository

CodeCommit repositories are automatically encrypted at rest. No action is needed from the customer in this regard. CodeCommit also encrypts data in transit automatically. The first time we create a repository in CodeCommit, CodeCommit creates an AWS-managed key (`aws/codecommit`) in the same region and stores it in your AWS account. CodeCommit uses this key to encrypt and decrypt the data in this and other repositories in the same AWS account. Please note that we cannot use a customer-managed key created in AWS KMS Service to encrypt or decrypt data in CodeCommit repositories.
